

ASSIGNMENT BY PAULINE NALUBAALE

1. Programming

Is the art and science of writing instructions to be interpreted by a computer. Its an art because similar instructions are written differently by different people. It's a science because it has principles and rules that have been set and we have to follow them

2. Relationship between CPU, RAM and Hard disk

Written instructions are meant to be stored on a hard disk and for the CPU to access these instructions, it goes through the RAM.

A CPU is basically a computer brain it executes the instruction. The RAM is a temporary memory for instructions and the Hard disk is a permanent memory.

3. Memory Address

This is a location on the hard disk where instructions are stored

4. Memory partitioning

This is a process of dividing the hard disk into memory units. An Operating system creates imaginary lines within the hard disk to create the memory units.

5. Variables

These are units of memory that have been named

6. Statement

This is a line of instructions consisting of a variable , operator and operand

7. Module

This is a python file. Its also known as a script. It has an extension of .py

8. Code

This is a collection of statements

9. Block of Code

These are related statements that perform a given task

10. Data type

These are formats of data that python understands. Data can be presented as countable numbers, alphabetical letters, decimals among others. Take an example, countable numbers are categorized as integers, alphabetical letters as strings

11. Declaring

This is the process of assigning a memory unit to a variable

12. Initializing

This is where we assign a value to a variable
