

**Assuming you are to discuss the following terms to a boda guy. with examples, define the following:**

**programming;** is the way in which different instructions are written in different languages telling a computer what to do. Let's take an example of Uganda which has people speaking different languages and we want to send a specific message maybe a good morning message in luganda, alur, lusoga, acoli, ateso, among the many. for all the mentioned languages, the tones will sound different but at the end of the day the message is the same and we'll find that some tribes will kneel and others may not mind. that is programming

**relationship between the CPU, RAM and the Hard disk:** a man heads a family, second in command is the wife and then the child. Let us say you are a father who left your child and the mother at birth; no connection was established at all. after some years of thinking and finding out that things are not easy outside you come back home and now you want to take care of your child.at that point, you will have to pass through the mother to provide for the child. you'll never reach the child directly.in this case, the father becomes the CPU the mother the RAM and the child the hard disk. Data in the hard disk can only be reach the CPU via the RAM because the CPU is not directly connected to the hard disk. the only way in which the instructions reach the RAM is by the OS which become the mother's words to the child.

**Partitioning:** is the process of creating smaller spaces of memory within a large unit of space. Let's say you have a piece of land and you have four sons and you'd want to share your piece of land among them, the way in which you will divide the land amongst them is partitioning

**Memory address:** is a named memory space by the computer. Say you are the computer and you have to name pieces of land in preparation to give to your sons respectively and you called these pieces of land Ekyamere, Eky'okuzimba, Ekyokupanga and Ekyabyona. those names given to the divided pieces of land become memory addresses because you are the computer named them.

**Variable:** is another name given to a memory address to ease remembrance on the end of the programmer. For example, you have customers that you transport and they have the names of Kicapalubanga, Ngamatekloyuyesu, Kerpamungubedi, Mungutekandha, these names are very long and hard to remember but then they say you can shorten the names to ease your remembrance and you'd Kica, Ngamatek, Ker and Mungu respectively; these become variables. In the case of the piece of land, let's say after dividing and giving them out, the children will not retain those names you gave, they will name them better and in an easier way.

**Statement:** is a complete written instruction to a computer. For example, let's say a child is the computer and you tell the child to go, the child will ask you to where or rather the child will not do anything because the instruction was incomplete but if you told the child to go and bring you a black piece of cloth on the grey suitcase in the bedroom; that becomes a statement.

**Module:** is a part of an entire program that performs a specific task and contribute to the wholeness of a thing. Let's say you build a house without a toilet be it outside or inside, at that point the house is complete but there is a specific room that carries out a specific function that is missing.

**Code:** is a group of complete instruction telling a computer what to do. For example, you telling your child to run and buy what to eat for breakfast, buy charcoal for 5000, waking up to bathe. And the child's ability to do all that it has been told to do.

**Block of code:** is a group of related statements working together that performs a specific task. Let's say you aim at telling your child if they want to maintain good personal hygiene, you'd tell the child that once they wake up, they should bathe, brush their teeth, comb their hair, put on fresh clean clothes, make their bed just to ensure that personal hygiene is being done.

**Datatypes:** these refer to the different kind of instructions. Assuming you are to discuss the following terms to a boda guy. with examples, define the following:

**programming;** is the way in which different instructions are written in different languages telling a computer what to do. Let's take an example of uganda which has people speaking different languages and we want to send a specific message maybe a good morning message in luganda, alur, lusoga, acoli, ateso, among the many. for all the mentioned languages, the tones will sound different but at the end of the day the message is the same and we'll find that some tribes will kneel and others may not mind. that is programming

**relationship between the CPU, RAM and the Hard disk:** a man heads a family, second in command is the wife and then the child. **Partioning: is the process of creating smaller spaces of memory within a large unit of space. Let's say you have a piece of land and you have four sons and you'd want to share your piece of land among them, the way in which you will divide the land amongst them is partioning**

**Memory address: is a named memory space. Say after dividing your piece of land in preparation to give it to your sons respectively and you called these pieces of land Ekyamere, Eky'okuzimba, Ekyokupanga and Ekyabyona. those names given to the divided pieces of land become memory adresses.**

**Variable: is another name given to a memory address to ease remembrance on the end of the programmer.For example you have customers that you transport and they have the names of Kicapalubanga, Ngamatekloyuyesu, Kerpamungubedi, Mungutekandha, these names are very long and hard to remember but then they say you can shorten the names to ease your remembrance and you'd Kica, Ngamatek, Ker and Mungu respectively; these become variables.**

**Statement: is a complete written instruction to a computer. For example, let's say a child is the computer and you tell the child to go, the child will ask you to where or rather the child will not do anything because the instruction was incomplete but if you told the child to go and bring you a black piece of cloth on the grey suitcase in the bedroom; that becomes a statement.**

**Module:** is a part of an entire program that performs a specific task and contribute to the wholeness of a thing. Let's say you build a house without a toilet be it outside or inside, at that point the house is complete but there is a specific room that carries ouut a specific function that is missing.

**Code:** is a group complete instructions telling a computer what to do. For example, you telling your child to run and buy what to eat for breakfast, buy charcoal for 5000, waking up to bathe.

**Block of code:** is a group of related statements that performs a specific task. Let's say you aim at telling your child to mainatin good personal hygiene, you'd tell the child that once they wake up, they should bathe, brush their teeth, comb their hair, put on fresh clean clothes, make their bed just to ensure that personal hygiene is being done.

**Datatypes:** these refer to the different kind of instructions we are going to write to a computer. Let's say your number plate, since it has both letters and numbers, it becomes an alphanumeric datatype, your name is a text datatype, your phone number becomes a numeric datatype.

**Declaring:** is the process of naming/ baptising a memory spcae. Remember the names you gave to the pieces of land that you divided, the way you called each piece of land in a sspecific way, what you did was declaring which we could also call baptising the pieces of land.

**Initialising:** is the process of assigning values to the named memory space. Even the bible says that the first born will be given a double portion meaning that as you divided the land, you knew which to give to each of your sons from the first to the last. let's say Ekyamere = 2acres, Eky'okuzimba = 3.5acres, Ekyokupanga = 3acres and Ekyabyona = 5acres, the way you gave values to every pice of land is initialising.

**Block of code:** is a group of related statements that performs a specific task. Let's say you aim at telling your child to mainatin good

**personal hygiene, you'd tell the child that once they wake up, they should bathe, brush their teeth, comb their hair, put on fresh clean clothes, make their bed just to ensure that personal hygiene is being done.**
